

IS ANTIMICROBIAL RESISTANCE INCREASING?

DATA SCIENCE PREP COURSE CAPSTONE PROJECT

Rich Gorham

<https://github.com/richardgorham1/ds-prep-capstone.git>

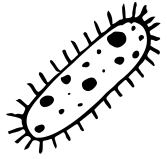

THE ISSUE

Arms race. Antimicrobial resistance is increasing worldwide.

Discovery void. Antimicrobial has substantially decreased since the mid 1990's.

World Health Organization. Antimicrobial resistance: global report on surveillance. World Health Organization 2014

THE ISSUE

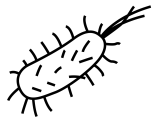

Mortality rates:

Circa 1920(EU and US): 30 per 10,000

Circa 1990(EU and US): 0.005 per 10,000

by 2050(WW): 20 fold increase

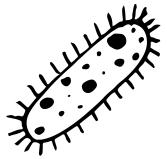

Runcie H (2015) Infection in a Pre-Antibiotic Era. J Anc Dis Prev Rem 3: 125. doi:10.4172/2329-8731.1000125

MONITORING EFFORTS

Worldwide, regional, and national monitoring.

National Antimicrobial Resistance Monitoring System
(NARMS)

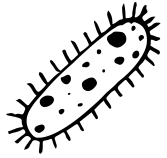

OBJECTIVES

- Look for general trends and patterns
- Interpret findings
- Develop proposal for future study / analysis

METHODS

- Manage data - Pandas
- Calculations, statistical and otherwise - Numpy, SciPy
- Charts and visualization - Matplotlib

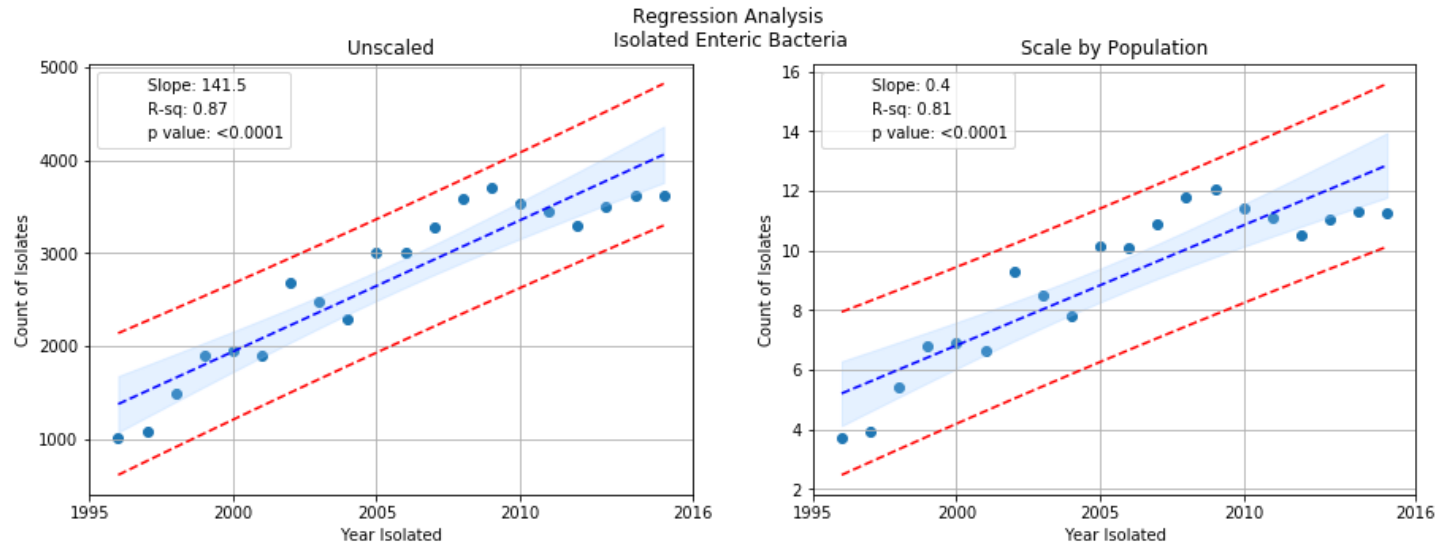

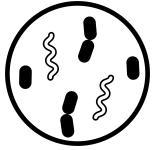

ENTERIC BACTERIA DATABASE

The CDC's NARMS Enteric Bacteria Database:

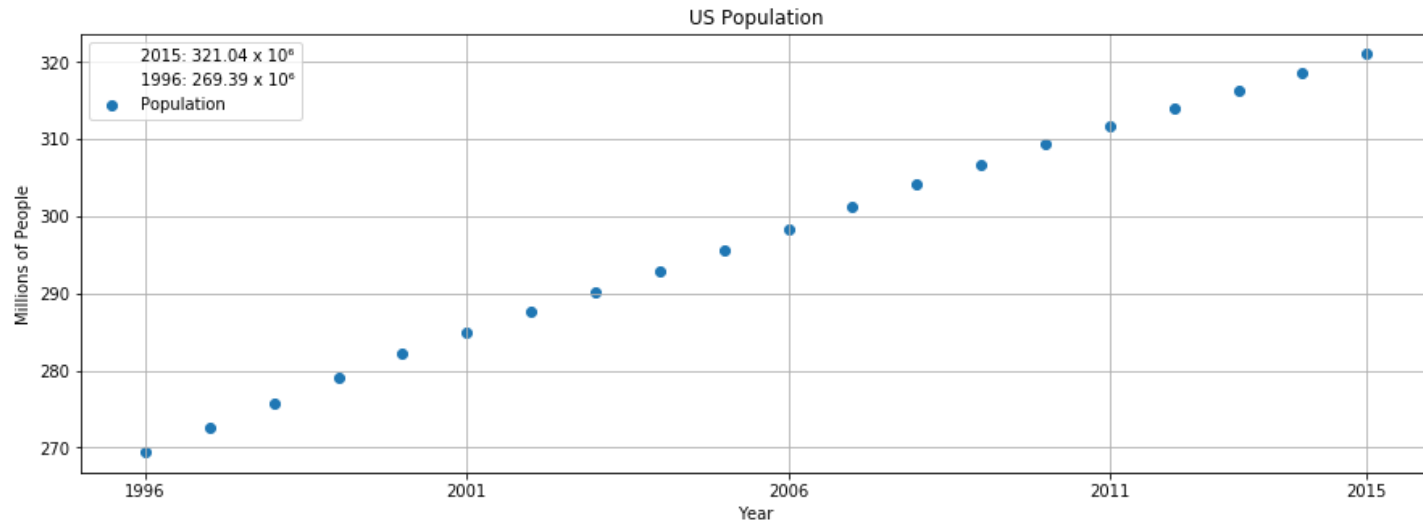

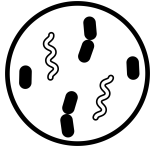

- Covers specimens collected from 1996 to 2015
- Tests against 31 antimicrobials
- Some resistome information

<https://wwwn.cdc.gov/narmsnow/>

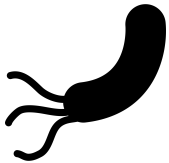

Set	Slope	Intercept	R ²	p for Regression
unscaled	141.5	-281056.13	0.87	<0.0001
scaled	0.4	-799.04	0.81	<0.0001

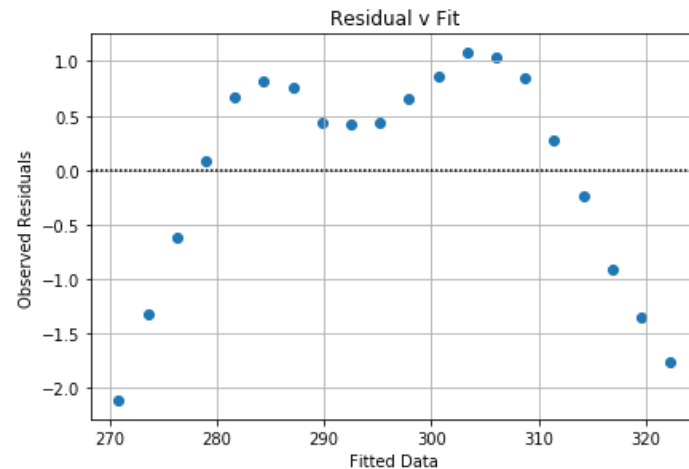

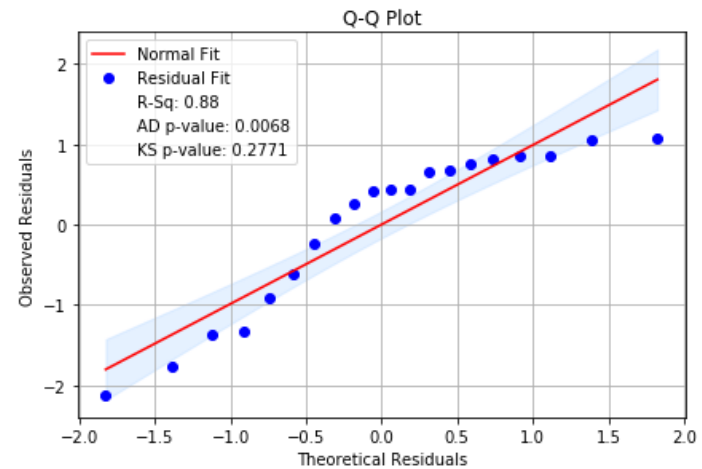

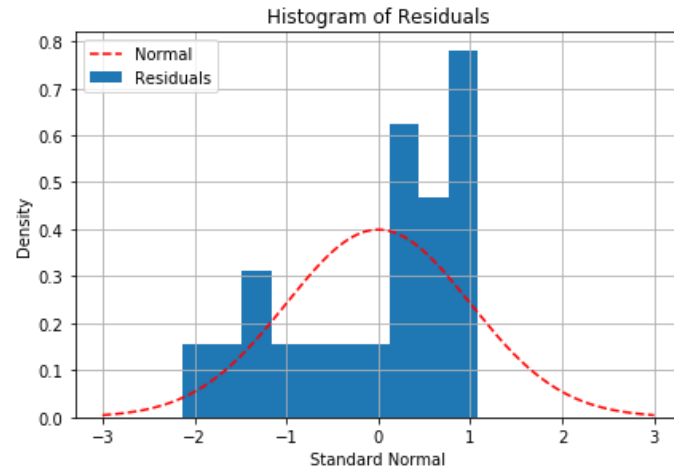

Scatter plots of enteric bacteria with regression, and prediction and confidence limits, unscaled and scaled to US population for the same period.

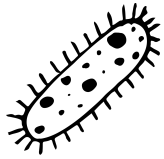

Scatter plot of US population, 1996 to 2015. The scatter looks linear, analysis below shows otherwise.

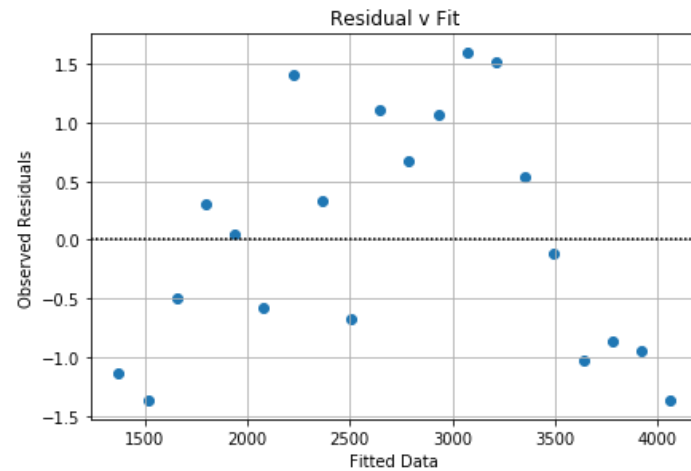

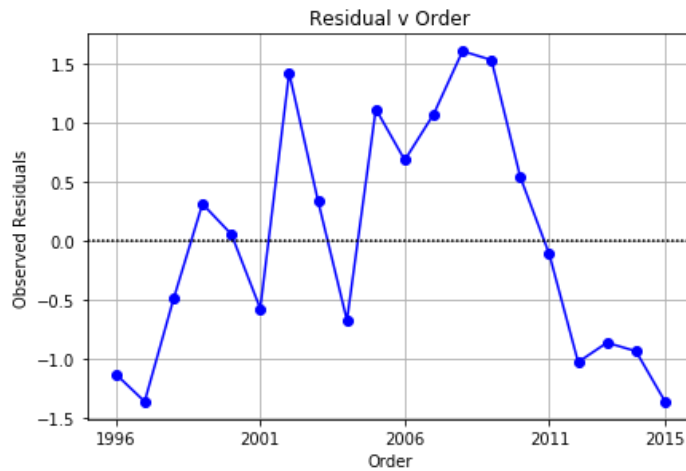

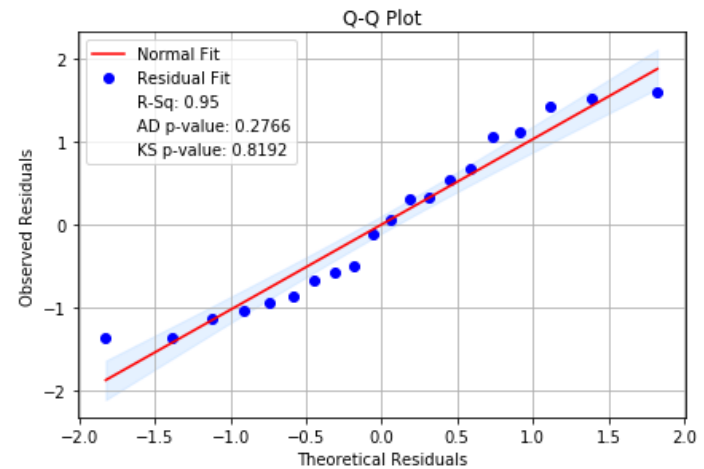

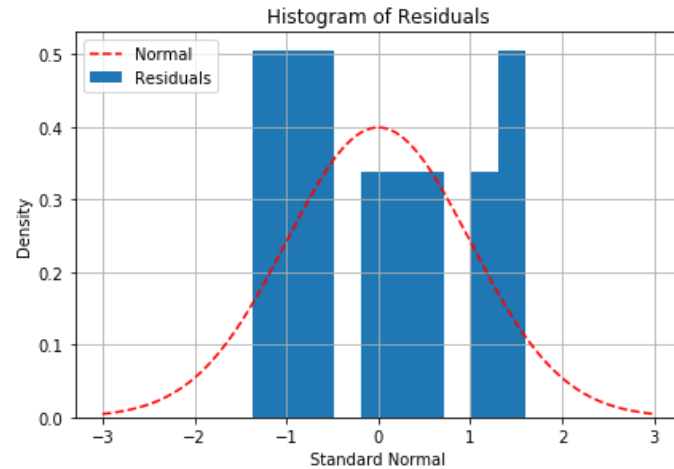

Residual Analysis Response is US Population

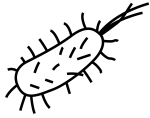

*Residual analysis for linear regression of US population.
The residuals do not prove to be normal and are not well dispersed.*

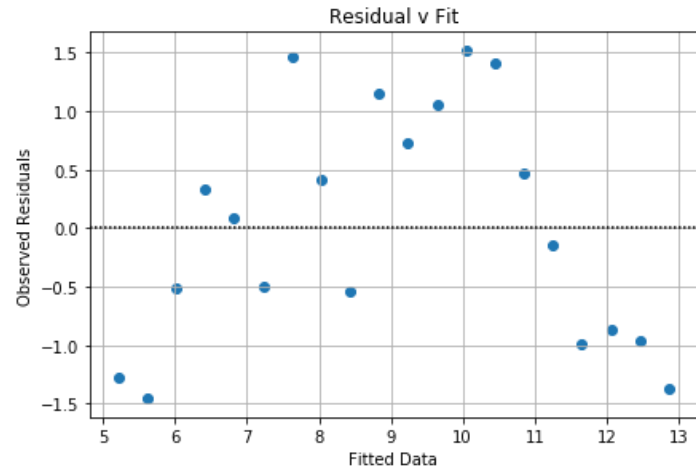

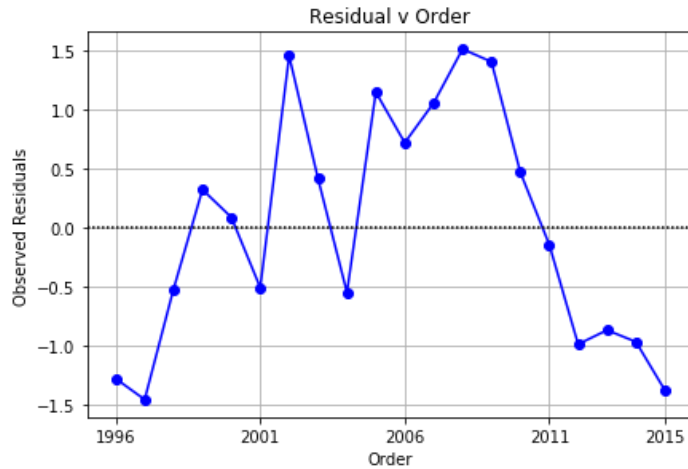

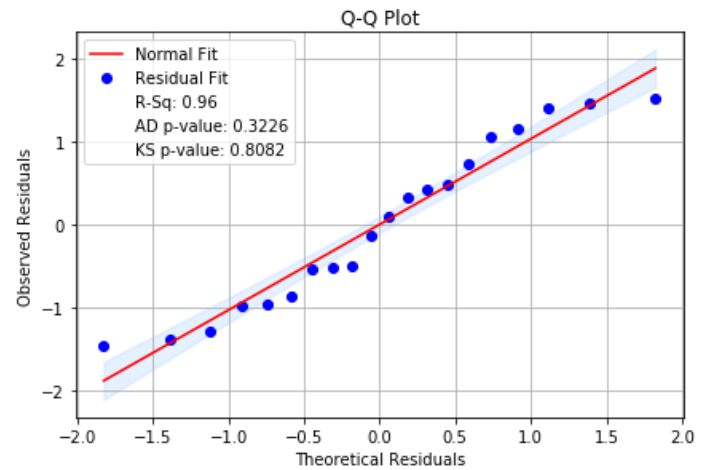

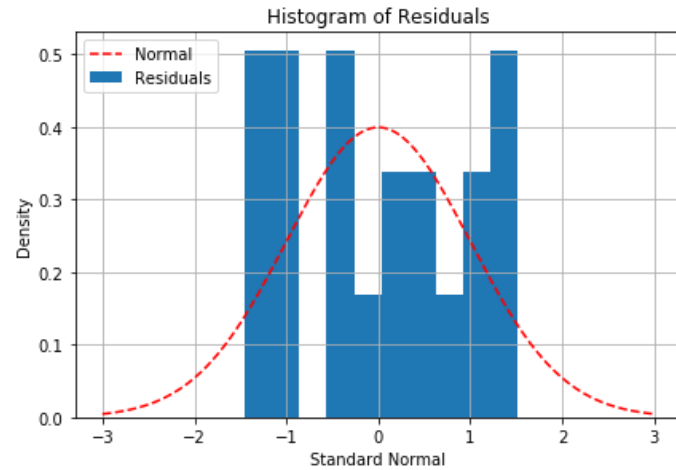

Residual Analysis Response is All Enteric

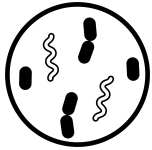

*Residual analysis for linear regression of all incidences of enteric bacteria.
The residuals prove to be normal and well dispersed.*

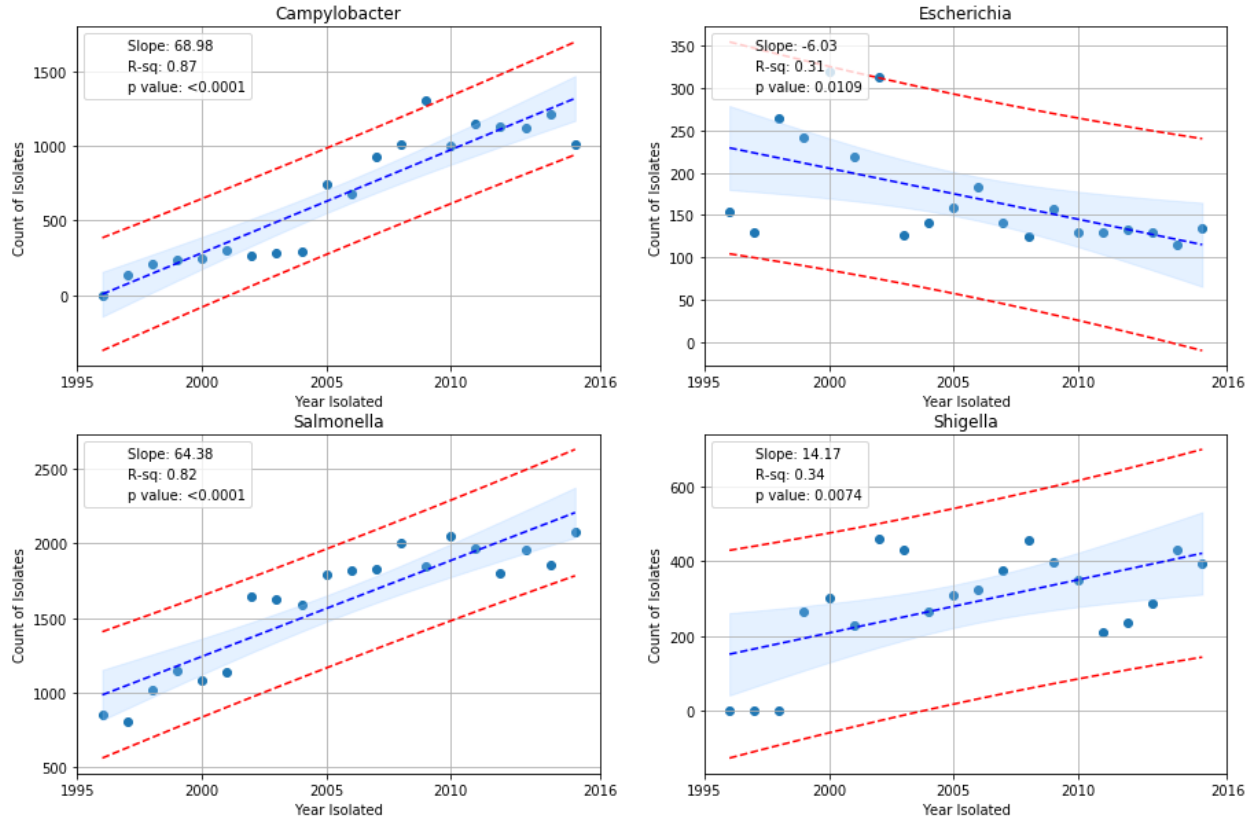

Residual Analysis Response is All Enteric per Million People

Residual analysis for linear regression of all incidences of enteric bacteria, scaled to US population. The residuals prove to be normal and well dispersed.

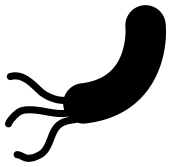

Regression Analysis Isolated Enteric Bacteria

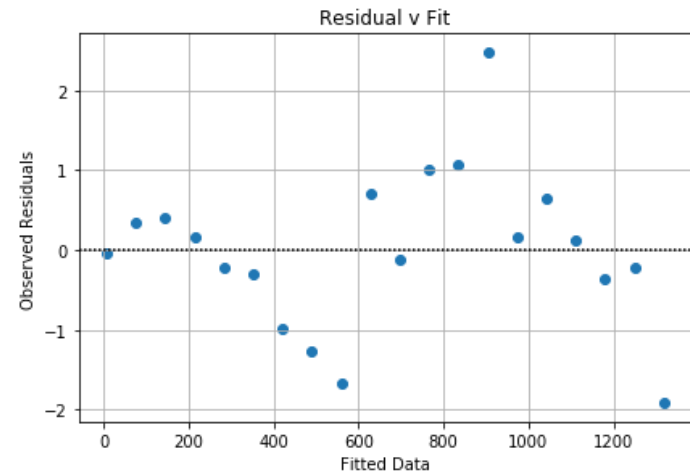

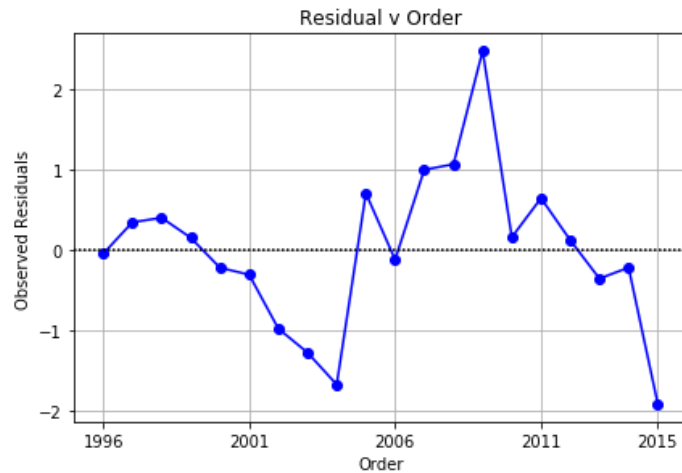

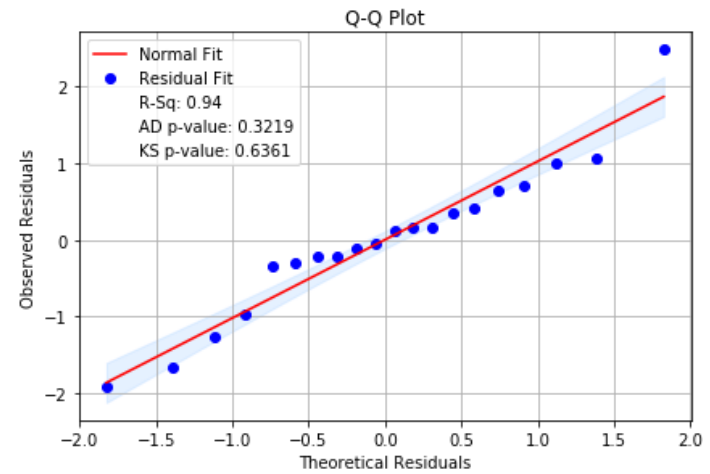

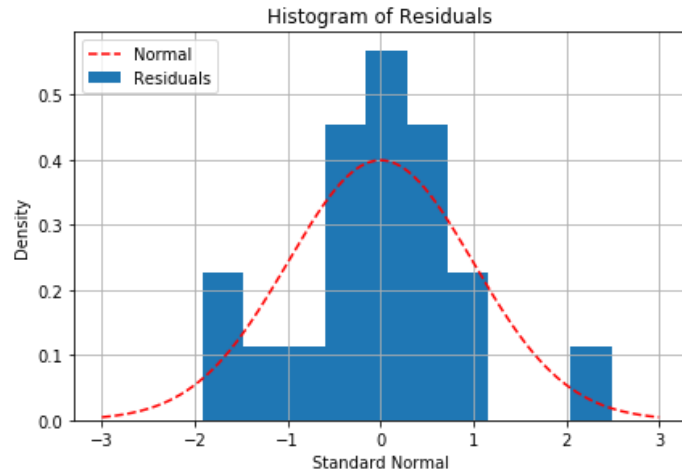

Set	Slope	Intercept	R ²	p for Regression
<i>Campylobacter</i>	68.98	-137682.27	0.87	<0.0001
<i>Escherichia</i>	-6.03	12267.0	0.31	0.0109
<i>Salmonella</i>	64.38	-127514.02	0.82	<0.0001
<i>Shigella</i>	14.17	-28126.91	0.34	0.0074

Scatter plots for the four genera in the data set.

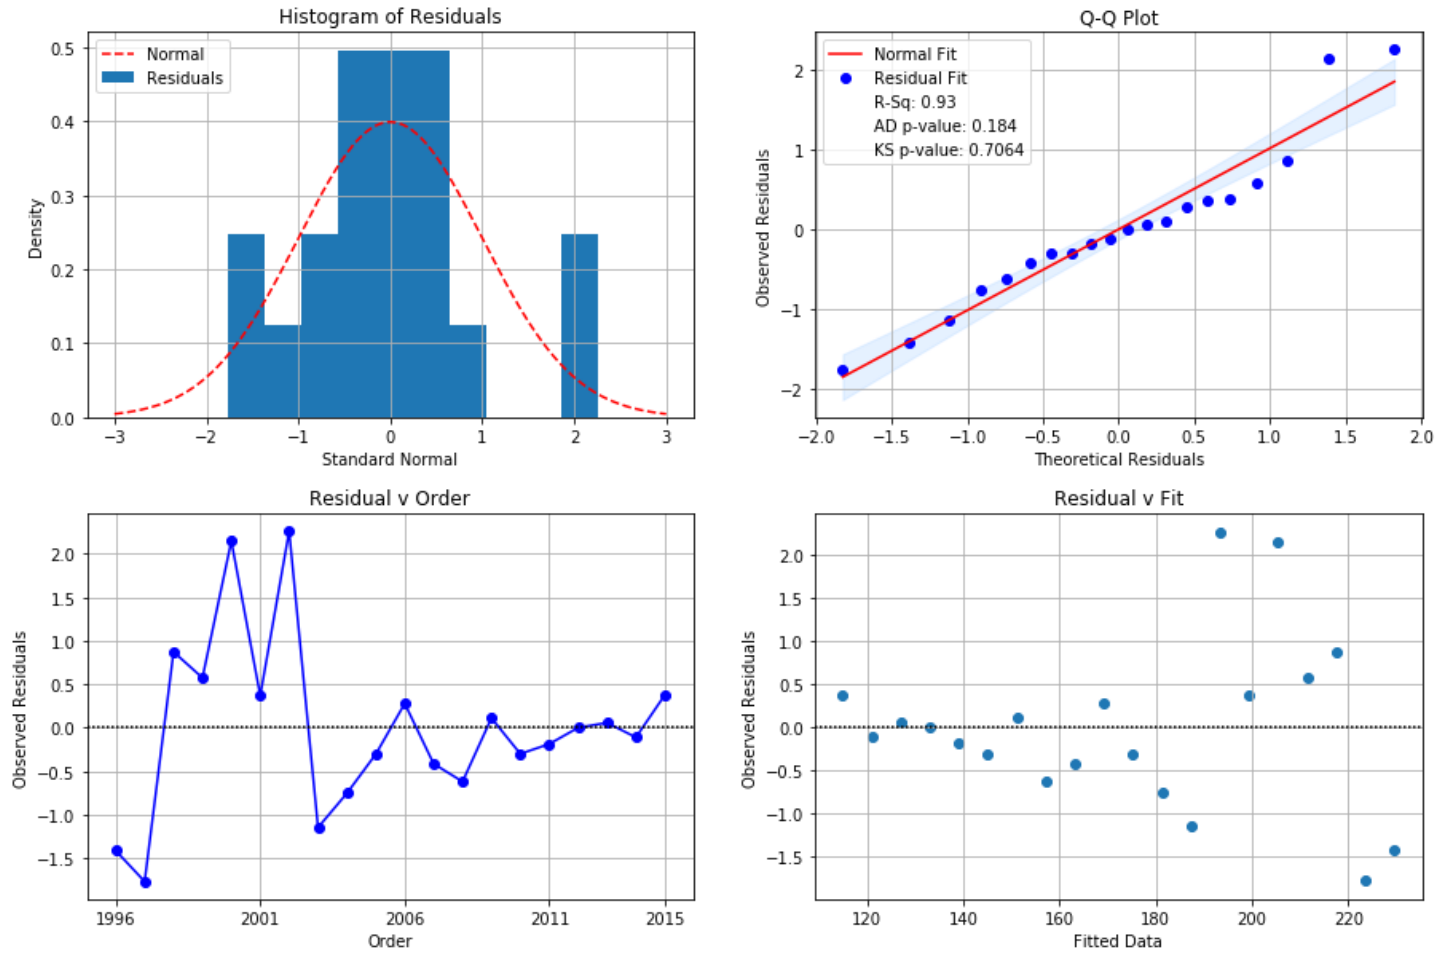

Residual Analysis Response is Campylobacter

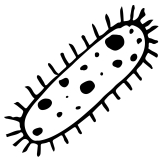

Residual analysis for Campylobacter. The residuals form a normal distribution and are well dispersed.

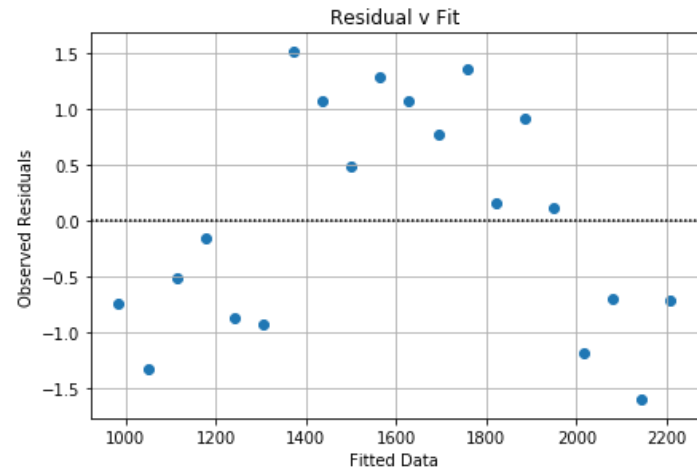

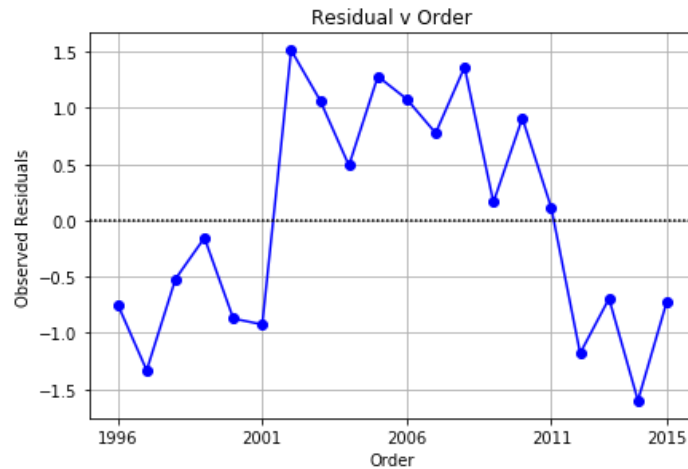

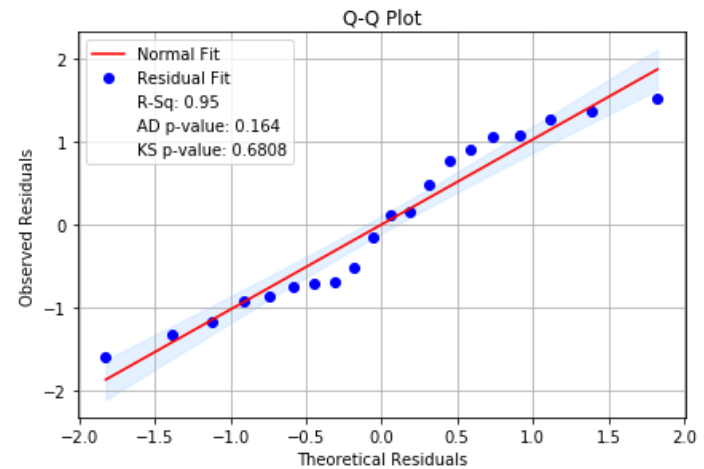

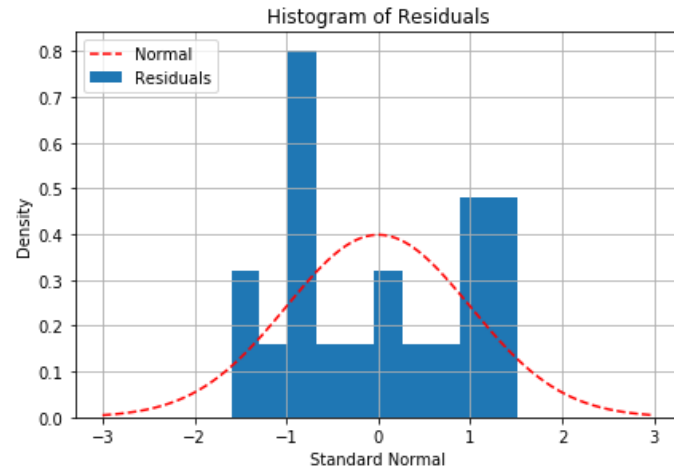

Residual Analysis Response is Escherichia

Residual analysis for Escherichia. The residuals form a normal distribution and are well dispersed.

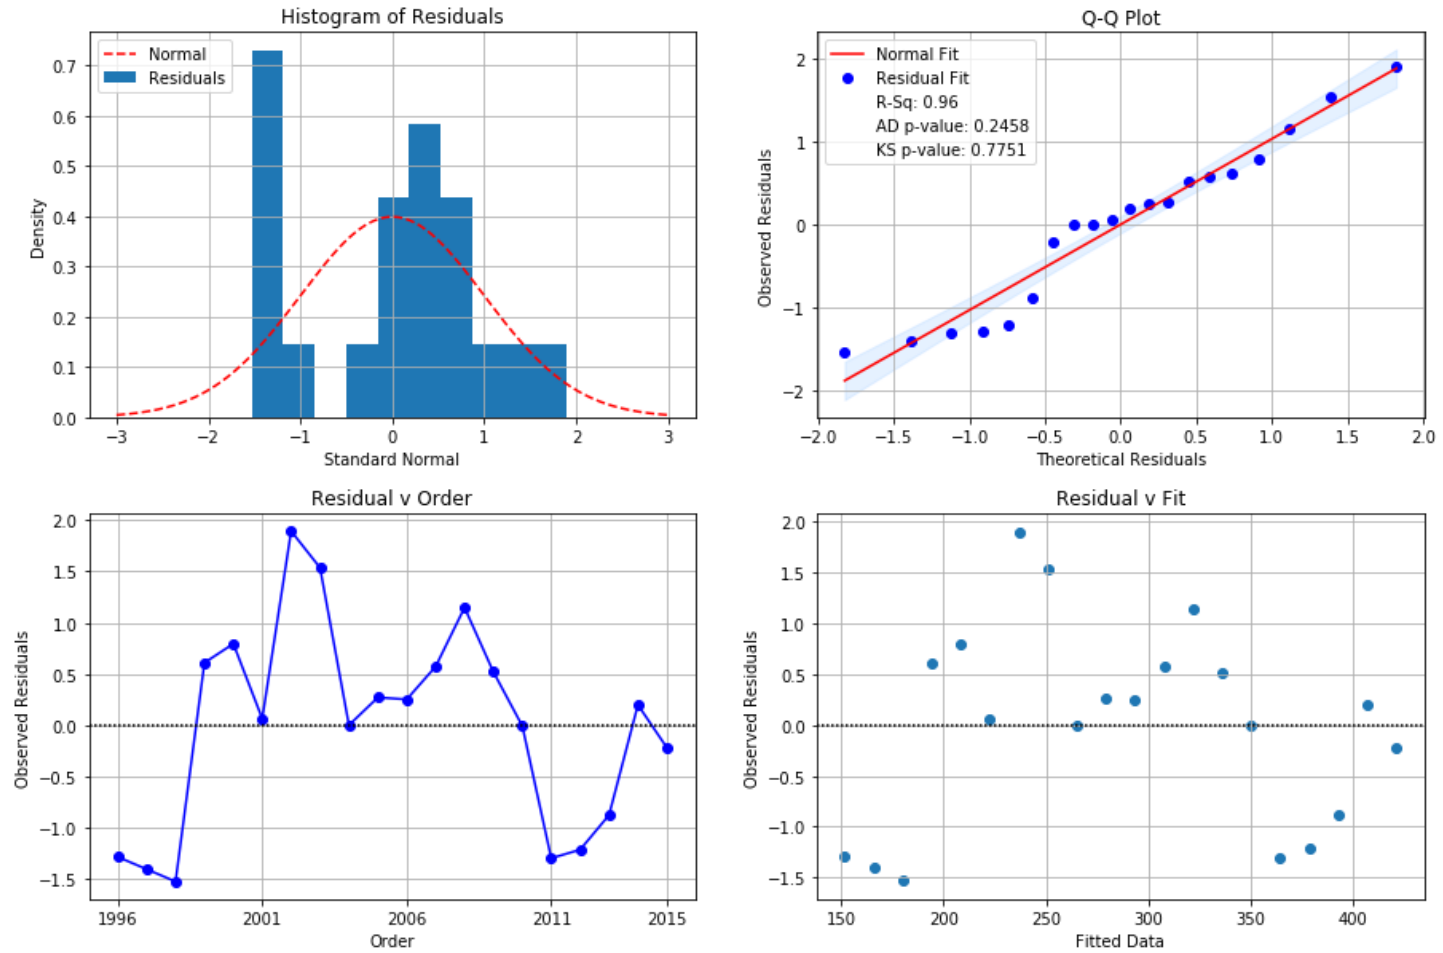

Residual Analysis Response is Salmonella

Residual analysis for Salmonella. The residuals form a normal distribution and are well dispersed.

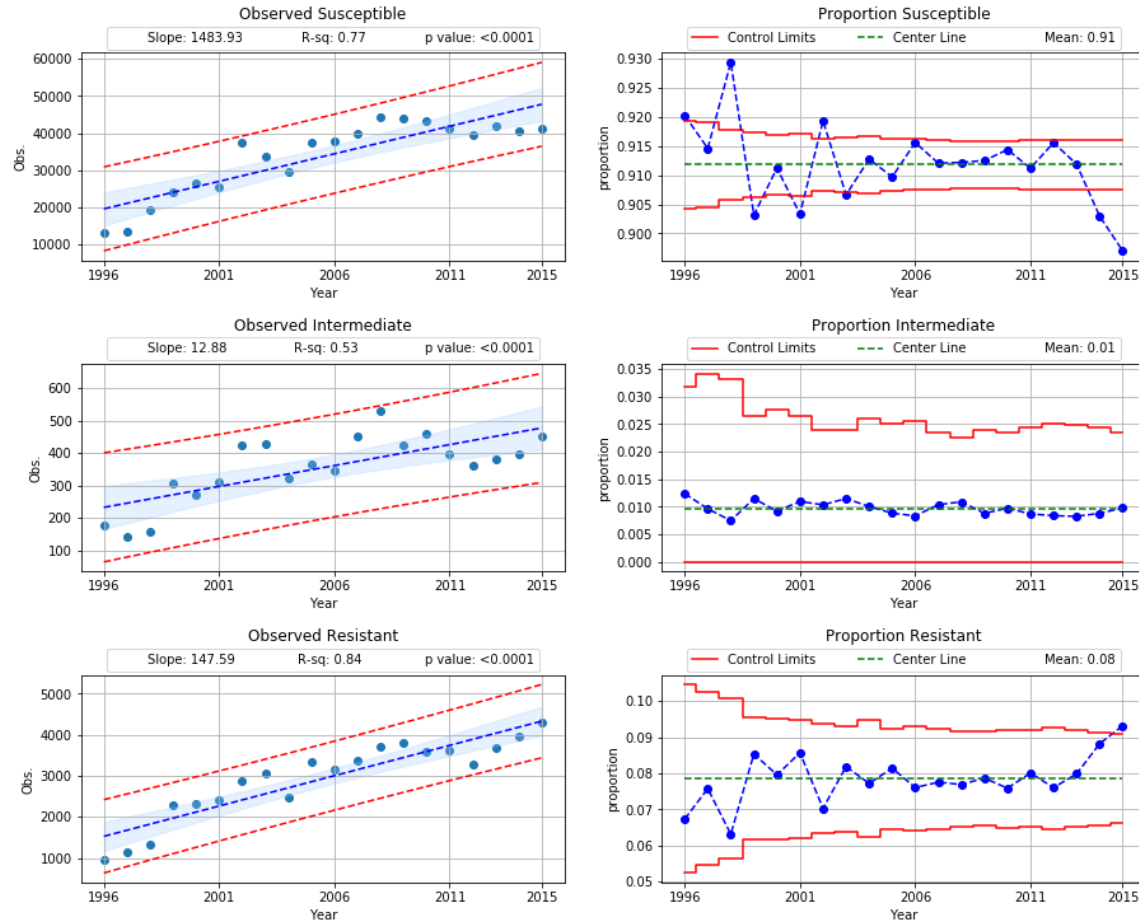

Residual Analysis Response is Shigella

Residual analysis for Shigella. The residuals form a normal distribution and are well dispersed.

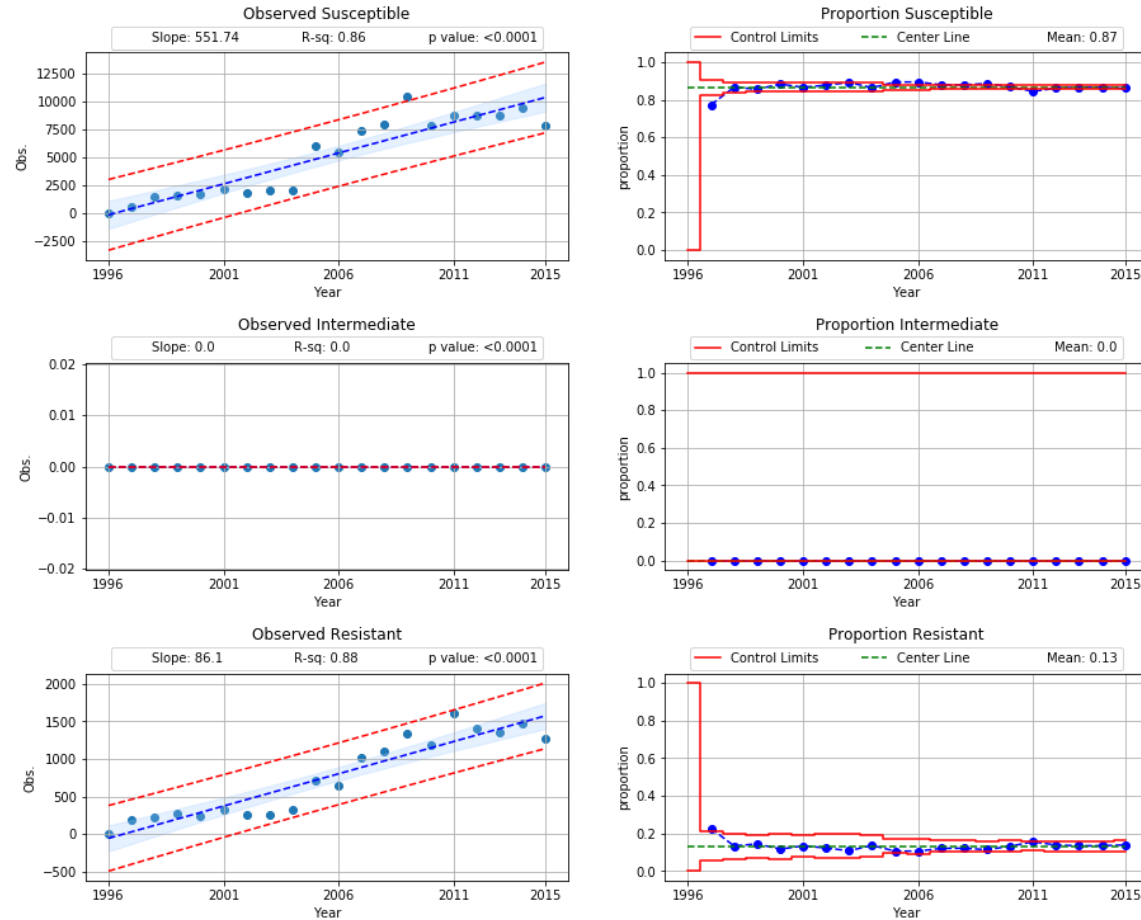

Regression and p Charts for Susceptibility / Resistance All Isolates

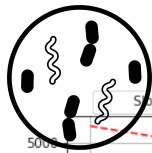

Scatter and proportion plots for all enteric bacteria. Note that the last few years show a decrease in susceptible isolates and corresponding increase in resistant isolates.

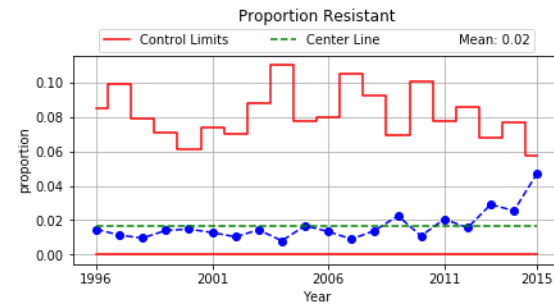

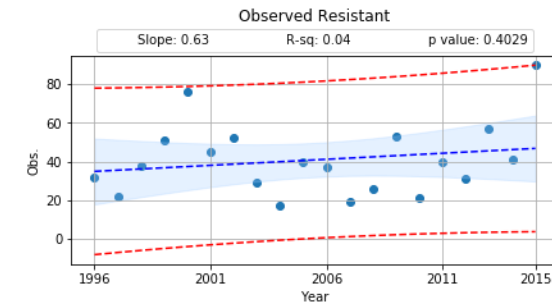

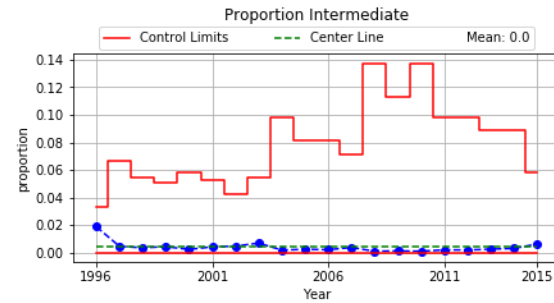

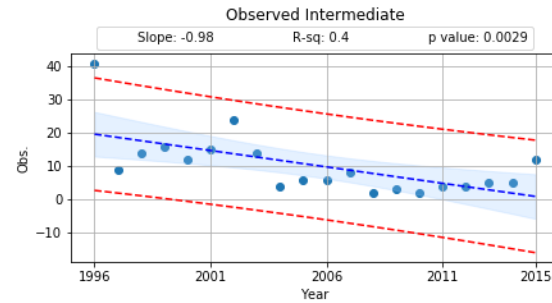

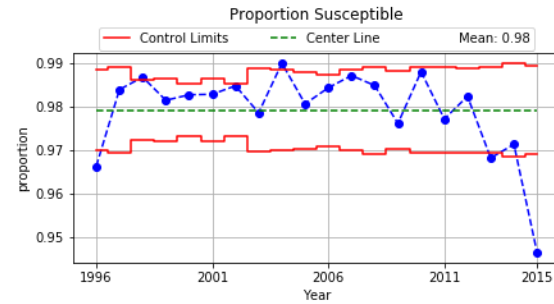

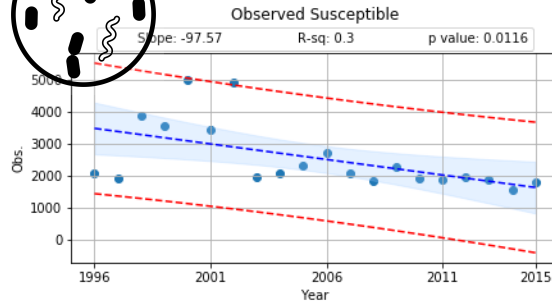

Regression and p Charts for Suceptibility / Resistance Campylobacter

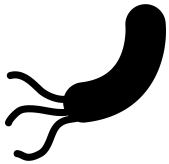

Scatter and proportion plots for Campylobacter. Note a rather stable proportion in resistance.

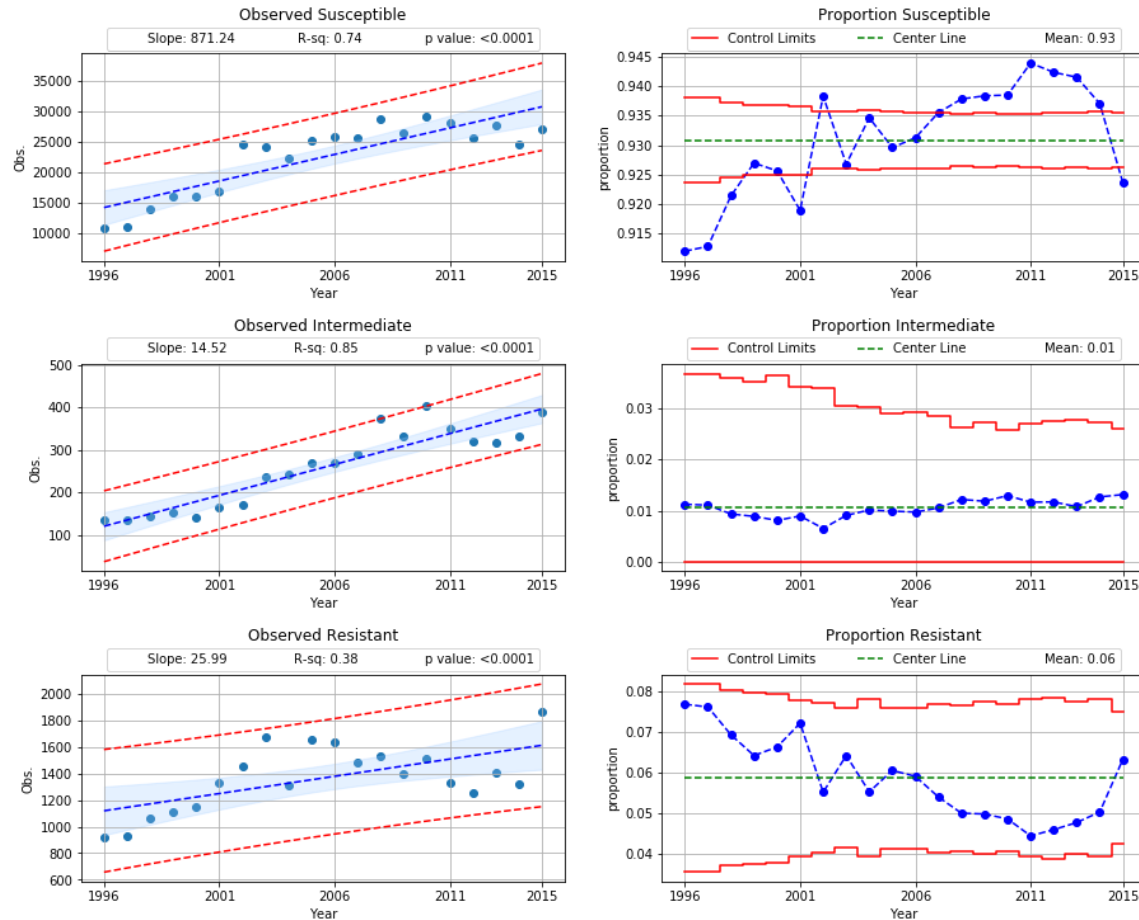

Regression and p Charts for Susceptibility / Resistance Escherichia

Scatter and proportion plots for Escherichia. There is some detectable movement between susceptible and resistant bacteria.

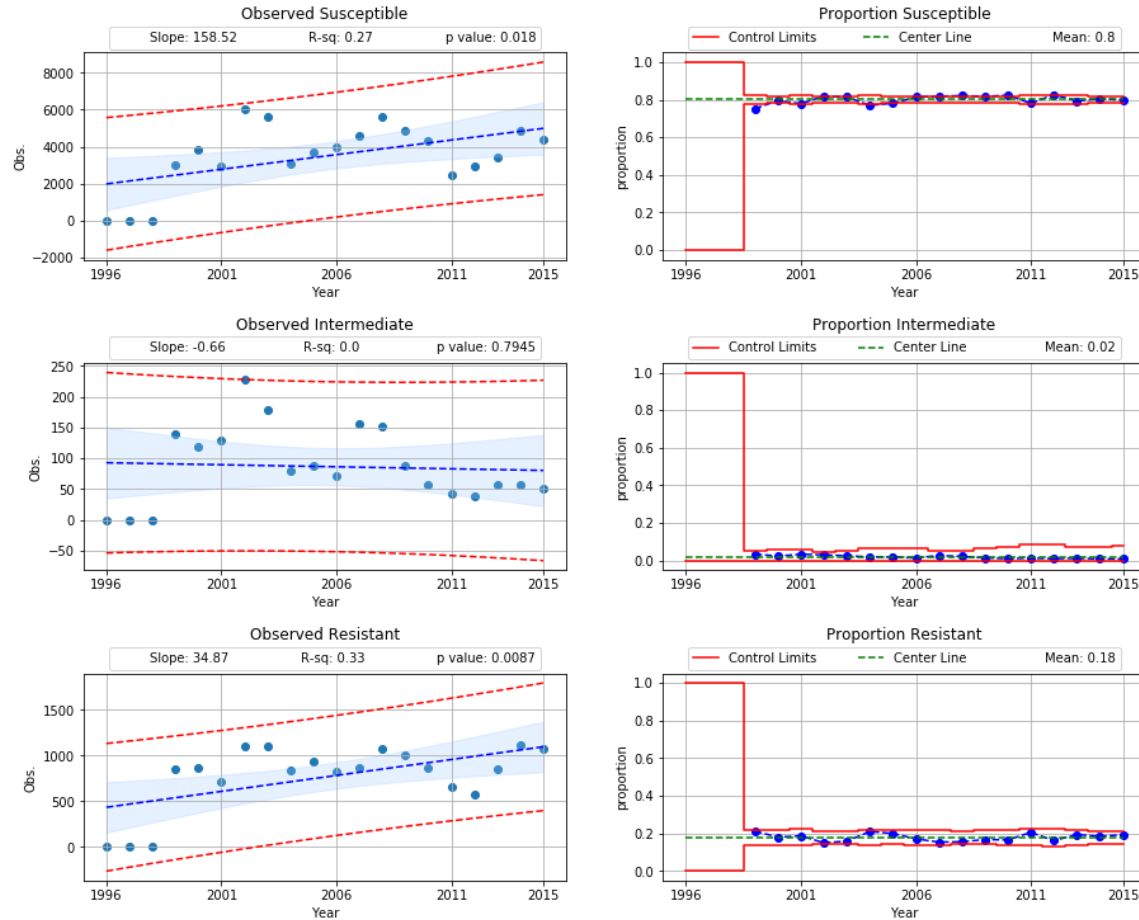

Regression and p Charts
for Susceptibility / Resistance
Salmonella

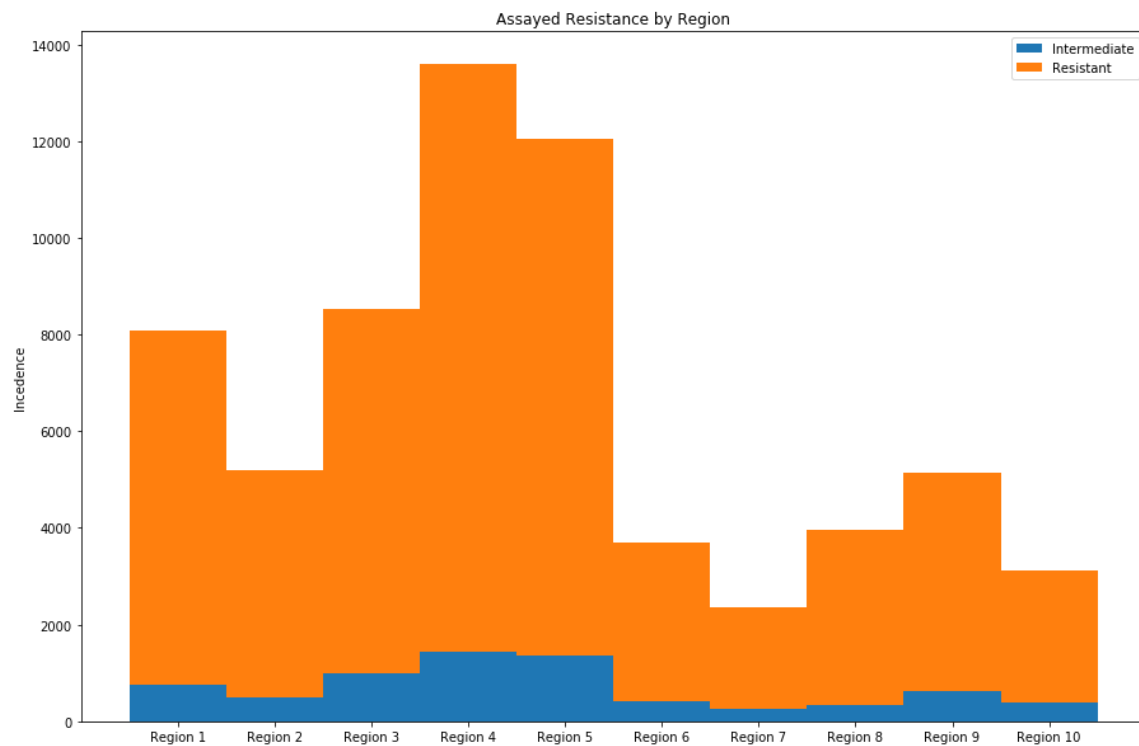

Scatter and proportion plots for Salmonella. There is some detectable movement between susceptible and resistant bacteria.

Regression and p Charts for Susceptibility / Resistance Shigella

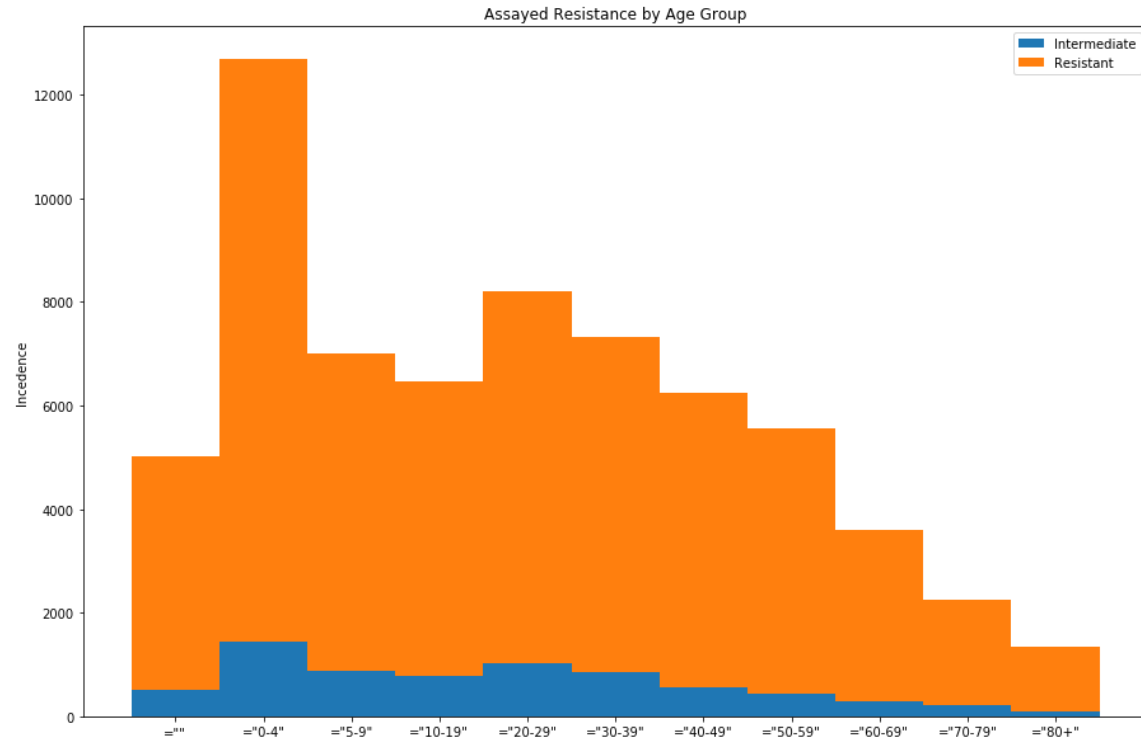

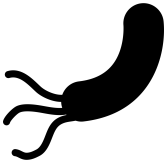

Scatter and proportion plots for Shigella. The proportions of susceptible and resistant bacteria are stable.

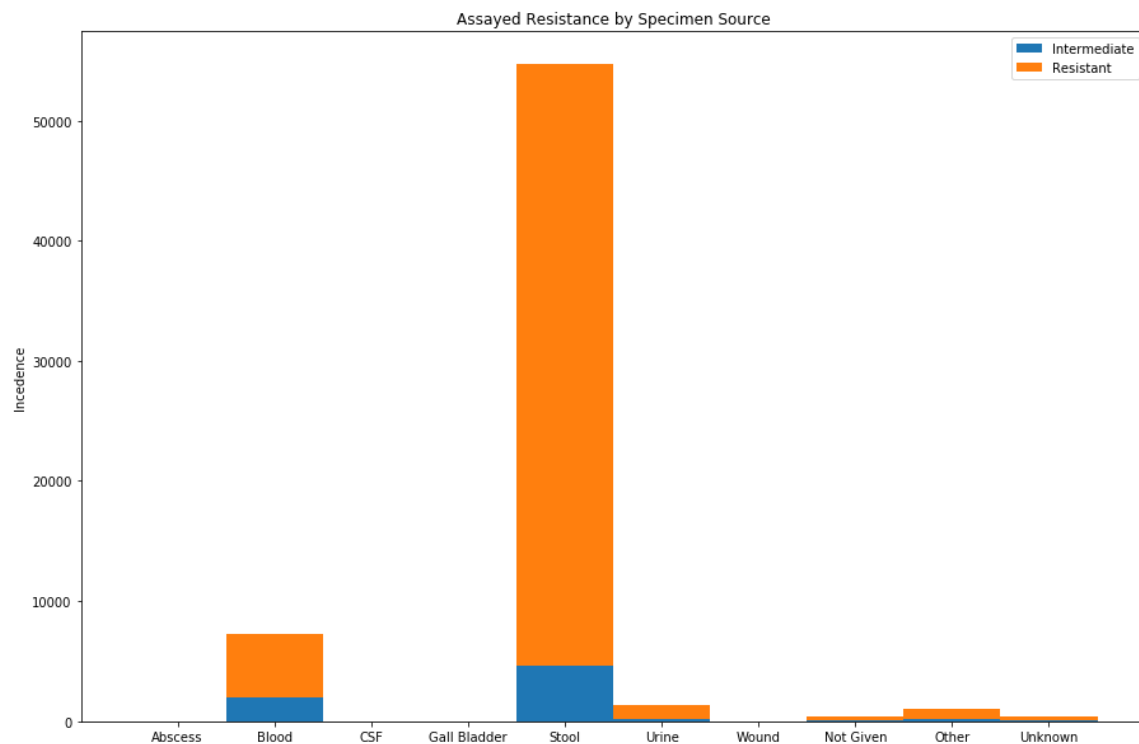

Differences observed between regions.

Set	Chi-Sq	p value
Intermediate	2,303	<0.0001
Resistant	18,184	<0.0001

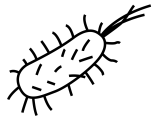

Differences observed between age groups.

Set	Chi-Sq	p value
Intermediate	2,465	<0.0001
Resistant	13,664	<0.0001

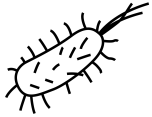

Differences observed from sepcimen source.

Set	Chi-Sq	p value
Intermediate	29,291	<0.0001
Resistant	376,847	<0.0001

CONCLUSIONS

- The observation of enteric bacteria has increased over the years, but this could be due to improvements to monitoring.
- There is some evidence that the proportion of resistance is increasing at least in some enteric bacteria.

PROPOSAL

- There is widespread concern about antimicrobial resistance.
- Good information about the prevalence of antimicrobial resistance is not available.
- Resistomes to most antimicrobials have been sequenced and identified.

Search a database of genetic sequences of enteric bacteria for the resistomes to develop prevalence information. Include both pathogenic and nonpathogenic bacteria.
